Abstract

In this project, we applied the skills developed through the course and reverse engineered the Wyze Sense Hub, a key component of the Wyze home security system. I began by testing connections to the UART, CJtag, and SWD interfaces. None were outputting useful information except for the UART connection with the EN25Q128 128 Megabit Serial Flash Memory and the Ingenic T31 processor. There we were able to see the startup behavior, and a login prompt. Unfortunately the login prompt had a unique password that was not able to be guessed with the information we had.

An interesting vulnerability was found in the open-source bootloader, U-Boot. By shorting the NAND flash just before the bootloader loads the firmware image, I discovered the system defaults to dropping back into the command line interface of the bootloader menu. From there I was able to access the root shell which was a squash file system (read only file system).

After gathering the information from both the UART startup, the bootloader menu, and root shell of the squash file system, I realized that altering the device's behavior could only be achieved by modifying the firmware directly on the chip.

Using hot air to get the chip off, I began by utilizing a universal chip programmer to read the contents of the serial flash EN25Q128 chip. Next I extracted the binary and analyzed the file systems, identifying potential vulnerabilities and key areas of interest. I was able to find many vulnerabilities within the filesystem that could be exploited including the ability to change or turn off the alarm, bypassing the password to the root shell, potential for sending logs to a remote server, and more.

This reverse engineering effort has truly deepened my understanding of how to attack

and defend embedded systems and provided a valuable experience in facing challenges seen in reverse engineering commercial devices.

Nomenclature

CLI	Command Line Interface
UART	Universal Asynchronous Receiver/Transmitter, a serial communication protocol
SDIO	Secure Digital Input/Output
CJtag	Constrained JTAG or Compact JTAG
SWD	Serial Wire Debug
NAND	Non-volatile flash memory storage
SquashFS	A compressed, read-only filesystem used in embedded devices
JFFS2	Log-structured filesystem designed for use on flash devices
U-Boot	A popular open-source bootloader in embedded systems
Li-Ion	Rechargeable battery
etc/shadow	Linux file that stores hashed passwords
chip-off	Physically removing a chip from the device's printed circuit board
inodes	Structure used in Unix-like operating systems to store information about files
SDIO	Secure Digital Input/Output

Chapter 1

Introduction

The Wyze Sense Hub is a pivotal component in the Wyze home security system. Malicious changes to this device compromises the entire system, rendering its security functions ineffective. Reverse engineering this device is crucial because there are many people who rely on this device for security, and if an attacker were able to modify the device, they could potentially cause significant harm.

The Wyze sense hub is known as "the brains behind the brawn". Its role is to connect the other components used to provide security for the environment. There are typically other components that will be bought with the sense hub like a keypad, entry sensor, motion sensor, climate sensor, and a leak sensor. These all combine to make the Wyze home security automation system, where the hub enables the smart home functionality, such as remote monitoring and control of the other components through the mobile app.

Reverse engineering the hub will allow me to understand its firmware, communication protocols, and how the device was developed, ultimately helping me reach the goal of implementing modifications to exploit vulnerabilities on the device.

1.1 Objective

The objective of this reverse engineering capstone was to identify vulnerabilities, and implement a persistent, stable, and stealthy modification. This project was split into three sections over the course over 40 days.

Phase 1: Analysis and Reverse Engineering

In phase 1 I spent the time pulling the firmware, analyzing the device behavior, and identifying vulnerabilities to exploit. This involved:

- Attempting to interact with the various communication and debug interfaces (UART, CJtag, SWD)
- Doing a chip-off firmware extraction by removing the EN25Q128 flash chip to gain access to the firmware
- Observe, analyze, identify, and plan for exploiting the potential vulnerabilities

Phase 2: Modification

In phase 2 I spent the time attempting modifications to the device based on the vulnerabilities that were identified. Attempting to implement them in various ways, primarily via the U-Boot bootloader, and by modifying serial flash memory.

Chapter 2

Background

2.1 Device Information

Identifying the software being used, **U-Boot** is an open-source bootloader often used in embedded systems to load the OS or firmware on startup. In the case of the Wyze Hub, U-Boot initializes the hardware components, loads firmware images and kernel modules.

The Wyze Hub uses a **squashFS filesystem** which is a compressed read-only filesystem often used in constrained memory systems like embedded devices. Any changes made to it are either not allowed, or not persistent.

2.2 Schematic and Components

The primary components on the device that should be focused on are the CC1310, Ingenic T31, and the EN25Q128 serial flash memory. All the components on the device are listed below.

- MotorComm - Low power single-port 10/100 Mbps Ethernet PHY
- TNK-BT16B03 - 100 base-t single port transformer module
- CC1310 - Sub-1 GHz RF device
- REALTEK 8189FTV - WLAN Network SDIO interface
- ETA6003 C213B - Switching Li-Ion battery charger
- A400cC - 3CH power management IC for applications powered by one Li-Ion batteries
- Ingenic T31 - Smart video application processor
- EN25Q128 - Serial flash memory

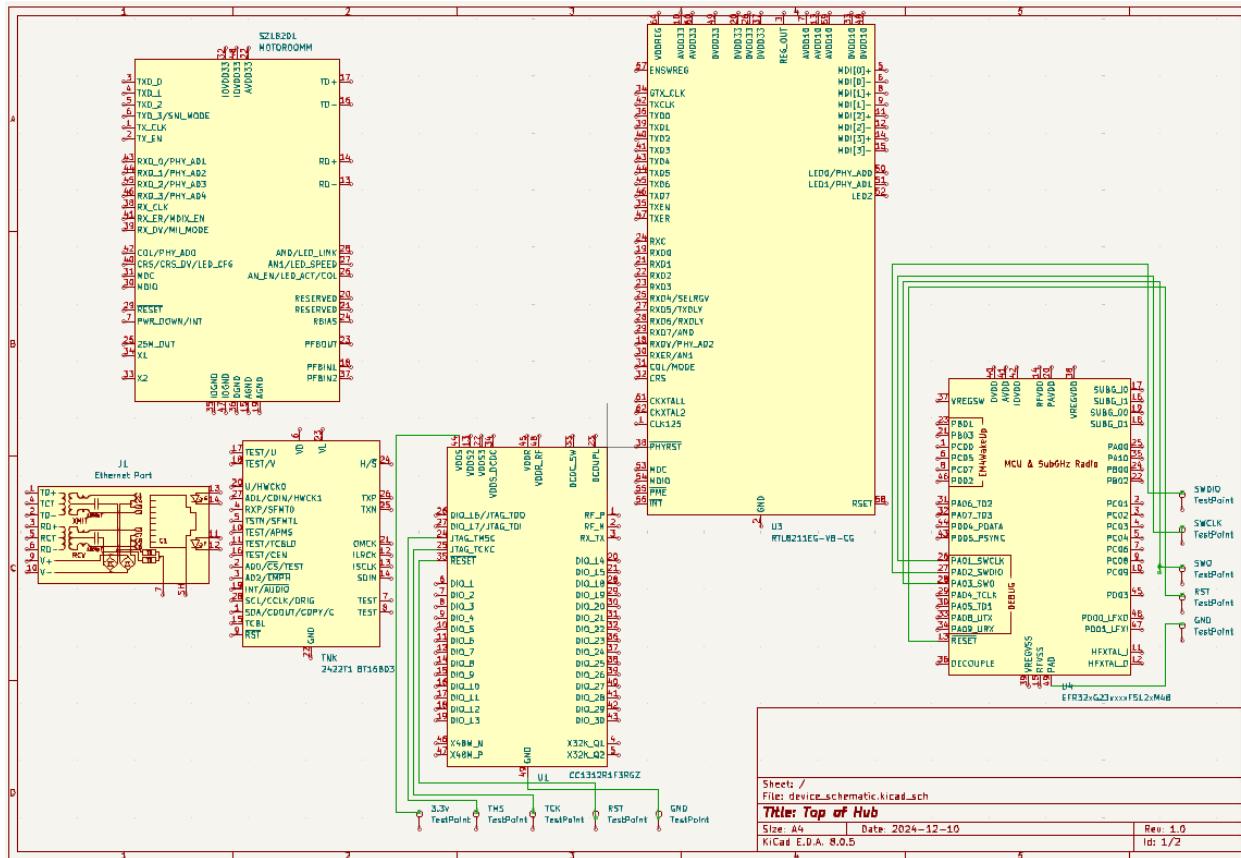

Figure 2.1: A schematic illustration of the top-level design.

2.3 Wyze Security Failures

Wyze has a history of shaky security engineering, their Wyze Cam was a very popular device due to the minimal difficulty to reverse engineer, and Wyze has also had instances where they have accidentally leaked private information of their customers to users of their devices. I chose this device because of their rather feeble security history, and due to the fact that there have been no public reports on the reverse engineering process of this device making this an interesting challenge.

Chapter 3

Analysis & RE

The first step taken in the reverse engineering process was to examine the communication and debug interfaces the hub was using. The components used, and pins visible support three options, UART, CJtag, and SWD. I invested significant amount of time attempting to connect with the CJtag interface on the CC1310 using the Segger J-link mini, but no output given in the console.

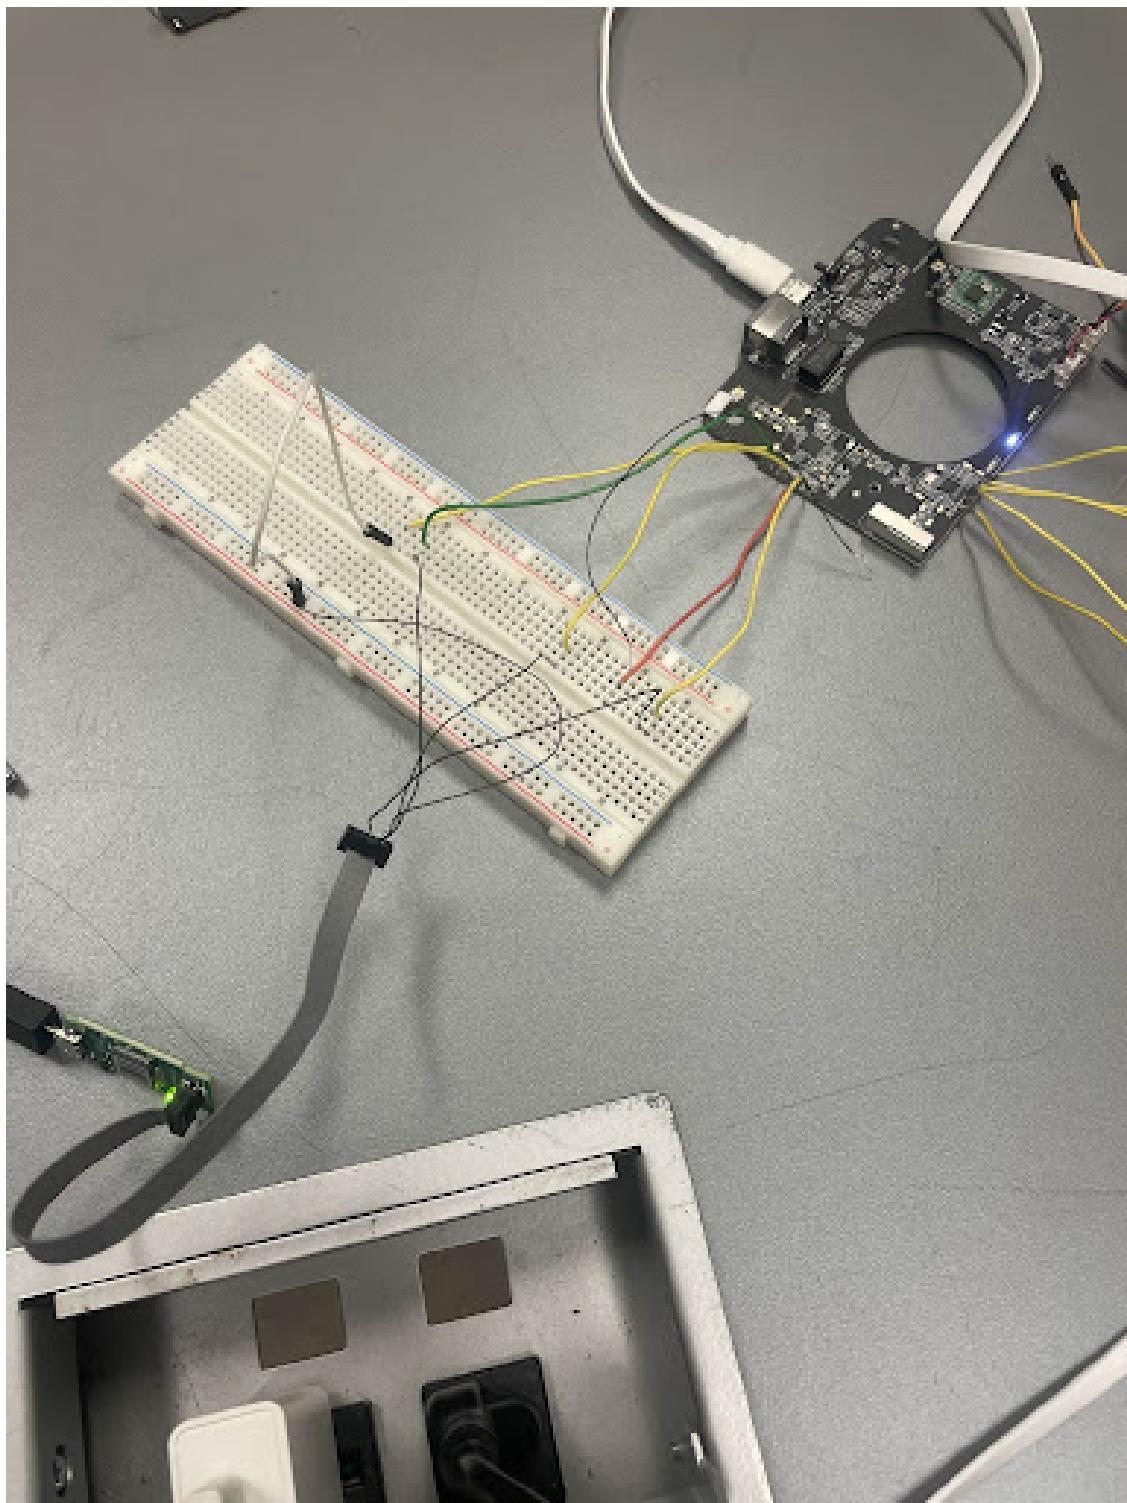

Figure 3.1: Attempted CJtag Device Connection

Attempting to interface with UART for the CC1310, only unintelligible data was shown

on device startup.

Figure 3.2: Output From CC1310 UART Interface.

The UART interface connected to the EN25Q128 128 Megabit Serial Flash Memory and the Ingenic T31 processor allowed useful data to be captured, including the startup behavior, and login prompt.

Figure 3.5: UART Startup

Observing the startup behavior, in figure 3.2, we can see that the open-source U-Boot bootloader is responsible for loading the firmware. During analysis, a vulnerability was discovered in the bootloader that allowed to bypass the reading of the flash memory, and force the system to drop into the bootloader's CLI by shorting the NAND flash right before the bootloader loaded the image into memory. I did this by soldering wire onto the "VCC" and "CLK" pins and touching them together just after the flash memory chip is recognized.

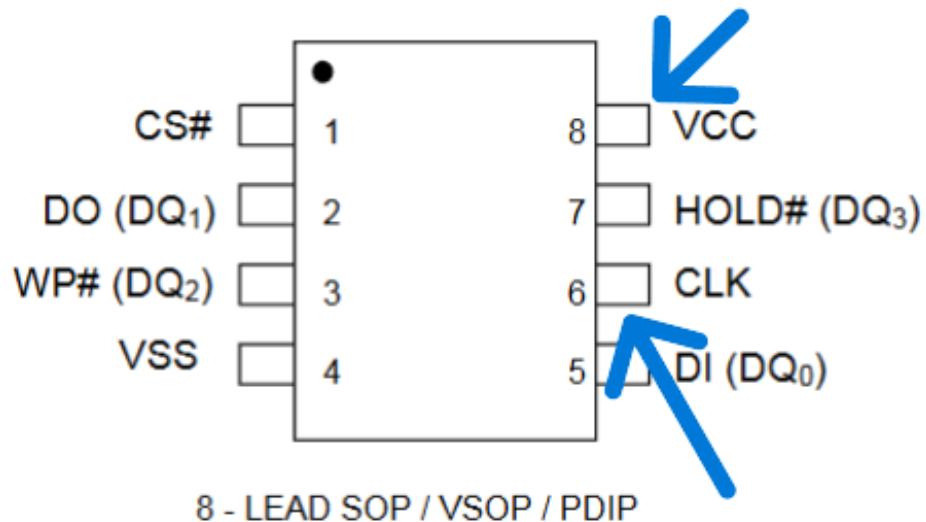

Figure 3.6: Pins Where Wire was Soldered

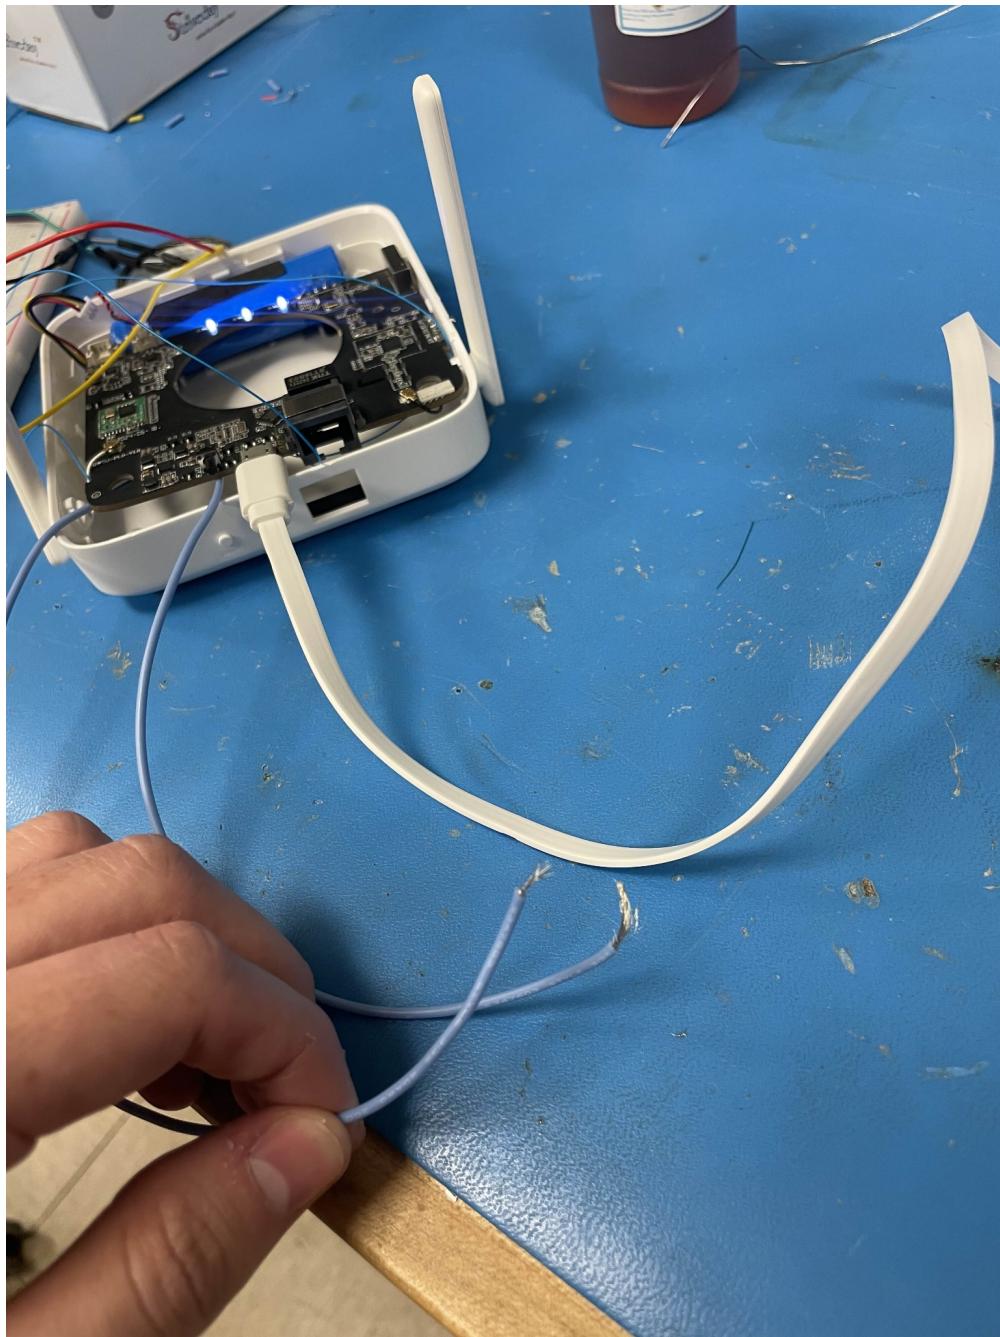

Figure 3.7: Wires Connected to Pins

This backdoor access to the U-Boot gives the attackers (us) to eventually enter a root shell on the device by changing the environment variables and rerunning the startup.

```

Figure 3.10: Root Filesystem

However, the root shell is a SquashFS file system, which by design is a read-only filesystem, meaning we will not be able to make any changes using this strategy.

Next I decided to do a chip-off to analyze the firmware further before deciding a modification plan. After getting the chip off the board using hot air and flux, I used a universal chip programmer to read the firmware.

Figure 3.11: A schematic illustration of the top-level design.

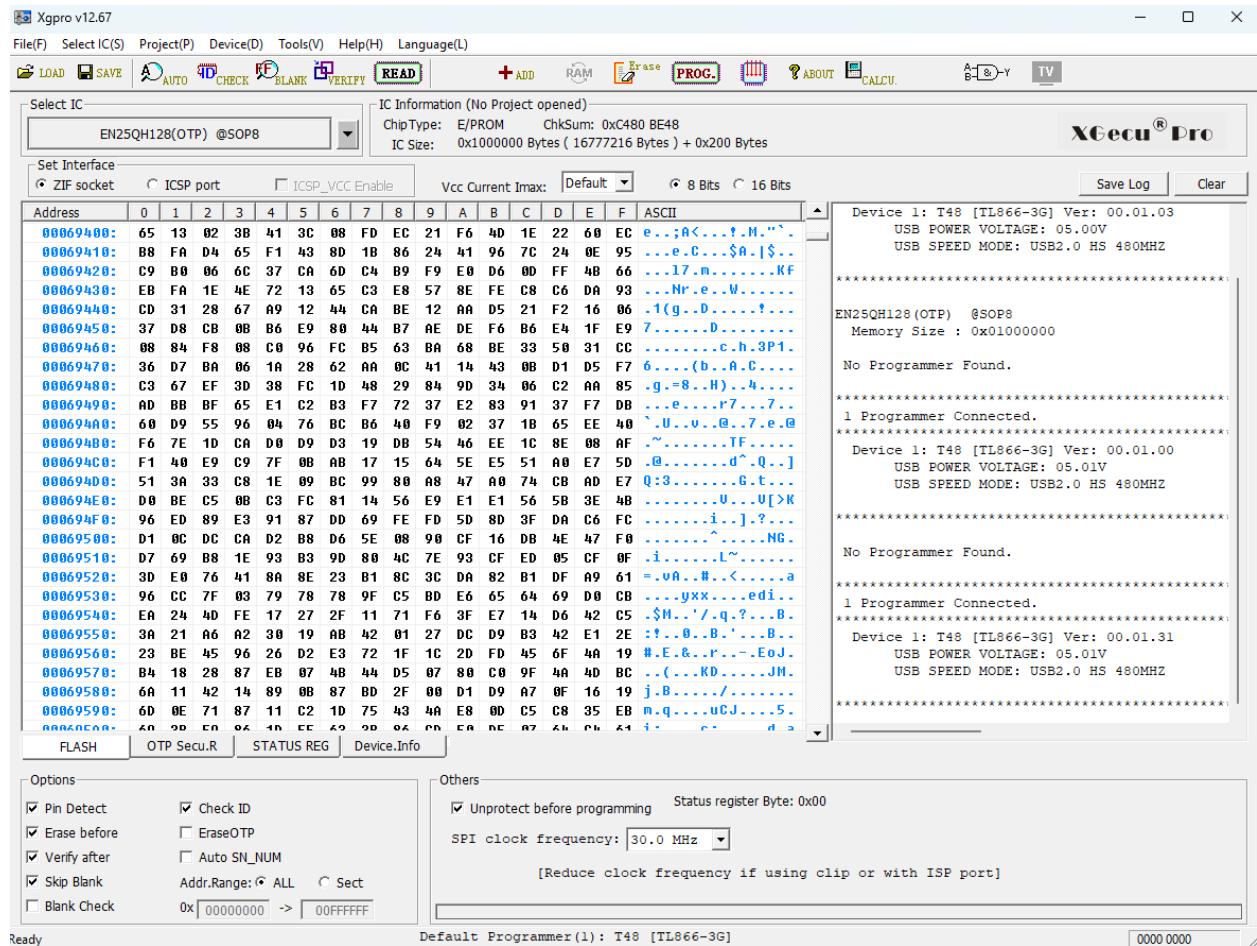

Figure 3.12: Firmware Binary in the Xgecu Software

Using the binwalk tool to analyze the firmware binary, we can see that the device utilizes a SquashFS filesystem, and a JFFS2 filesystem.

Figure 3.14: Firmware SquashFS Filesystem

There is a large amount of information to be gathered from the squashFS filesystems, there is the sound files for the alarms and system arming, startup scripts, network protocols and more. In the JFFS2 filesystem, it only contains the device version number.

Chapter 4

Modification

4.1 Attempted Strategies

So we know that the SquashFS filesystem is designed to be read-only, but if we are able to change it first then load the firmware image, that would allow us to successfully modify the system behavior.

There are two possible ways I can identify that we could accomplish that.

1. Modify the filesystem in the bootloader CLI
2. Modify the filesystem and load the new firmware onto the chip, then put it back onto the device board.

To start, I will need to make a modification to the SquashFS filesystem before attempting either of these. I chose to delete the password hash for the root user. I chose this because if I am able to successfully log in as the root user in the UART connection, it demonstrates that I can make further malicious modifications to the system.

```
brooks in classNotesFall2024/ere/capstone/chipFirmware/extract/modification/squashfs-root/etc on ↵ main [\$!?] ...
→ cat shadow
root::10933:0:99999:7:::
```

Figure 4.1: Modification to /etc/shadow

As mentioned previously, I was able to extract the firmware in a chip-off, for the first strategy I started by carving out a chunk of a filesystem I wanted to modify, make the changes, and repack it to match the original block size, byte length, and inodes.

Then using the same vulnerability of shorting the NAND flash to enter the bootloader CLI, I attempted to load a modification of the SquashFS file system directly into the serial flash memory using the U-Boot 'sf' serial flash commands.

```
isvp_t31# loady 0x80600000

Figure 4.2: Import Binary In Bootloader Menu

In Figure 4.2 it says it didn't load, but it clearly did into RAM in Figure 4.3 as shown in the farther offset. Then I erased the memory of the location at the first squashFS filesystem, and attempted to move the memory from RAM into the offset of the filesystem I wanted to replace, but as shown here, the data in that location is blank, showing it did not work.

```

Figure 4.3: Uboot Flash Modification Attempt

I suspect the reason is that the serial flash chips write protect is on. Based off the datasheet, the write protect is turned on when the #WP pin is grounded.

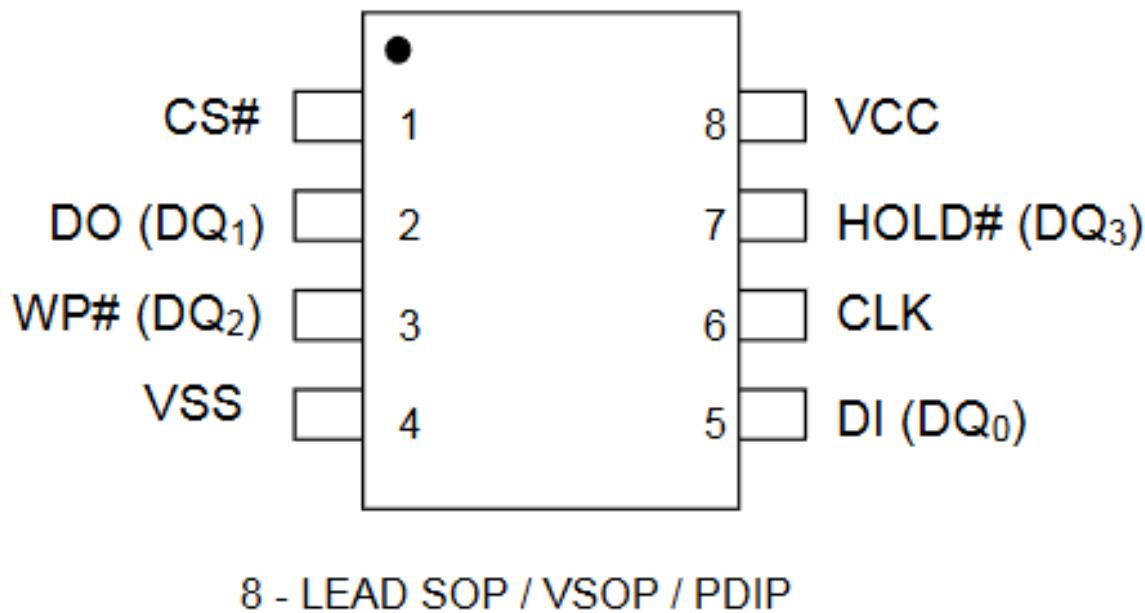

Figure 4.4: Flash Memory Pinout

With the time constraint, I was unable to figure out if there is a possible way to turn the #WP to high allowing the #WP to be turned off while loading the modified firmware image, but would like to explore further in the future if there's a possible workaround to bypass this issue.

Next I attempted the modification by changing the firmware, and loading it onto the flash chip. I attempted this two different times.

I first made my modification, to test I tried a simple change where I deleted the password hash from etc/shadow, so that when I was prompted to log in, I would be able to just press enter bypassing the password in the UART connection. As mentioned previously, I carved out the filesystem from the firmware binary, repacked it using the same compression tool, and inserted it back into the firmware image.

Figure 4.6: Modified Firmware Image

Looking at the offset for the first sequence of squashfs filesystems, we can see that it does not match the byte length of the original, or inodes, but the block size is the same. I figured that if the byte length is smaller, it wouldn't overwrite any data so it wouldn't affect the firmware being loaded.

However, after loading it back onto the chip, and starting up the device, it showed there was a failure in reading the index table.

```

Figure 4.7: Index Table Load Failure

4.2 Successful Modification

Initially, I was unsure of what exactly could be the problem, so before going to the U-Boot repository source code, I decided to try one more change that I thought could possibly be the issue, make my modifications so that each filesystem size matched the original.

I created a new firmware image, making the same change, but adding junk data (# characters) to various files to match the correct byte length, and inodes. So after applying the modification, making sure every measurement matched with the original binary, I loaded

the new firmware image onto the chip, and we can see that our modification of etc/shadow allow us to successfully bypass the password prompt, allowing us to login as the root user.

Figure 4.8: Successful Modification in UART Output

So using this method, we could make any alteration to the device by taking the chip off again, making a modification to the filesystem, ensuring that each filesystem size matches the original size, loading it onto the chip, and replacing it onto the PCB. Also, it is possible

that the initial failed attempt to load the firmware was somehow corrupted in the process, so it is not confirmed that the failure to load the ID index table was due to the nonuniform filesystem measurements.

Chapter 5

Conclusion

In conclusion, my persistent modification to the device was successful. I made great progress, encountered vulnerability discoveries, successfully reverse engineered the device and understood its behavior and layout, and successfully implemented a persistent modification to the device via chip off. This project provided great experience in reverse engineering a commercial device, faced challenges that real embedded reverse engineers see, and experienced the perseverance needed to be successful in this sector. I was able to gather useful information that would be helpful for anyone to know when reverse engineering this device in the future, and learned gained valuable experience making me a stronger reverse engineer. This was a very interesting project, one of my favorites I have ever done, and will continue to reverse engineer embedded devices in the future.
